

CpE 3201 Embedded Systems

Timers

Basic Concepts in Counters & Timers

Counter

- simply a register
- can be loaded with a binary count (can incremented or decremented at every clock pulse)
- Time is calculated by subtracting the beginning count from the end count and multiplying the difference by the clock period

Basic Concepts in Counters & Timers

- Example: if a counter is loaded with 100₁₀ and counts down to 00 and the clock frequency is 2 MHz, the time is calculated as follows:
 - Clock Period = $(1/f) = 1/(2x10^6) = 0.5$ us
 - Time = Difference in Counts x Clock Period =
 (100 0) x 0.5 us = 50 us

Basic Concepts in Counters & Timers

Event Counter

 the counter is triggered by an event instead of a clock such as a button push that increments or decrements the counter

Types of Counters and Timers

Up-counter

- this counter counts up at every clock cycle and when it reaches the maximum count, it resets back to 0 (overflow) which may set a flag or generate an interrupt signal; readable/writable

Down-counter

 counts down at every clock cycle and when it reaches 0, it may set a flag or generate an interrupt signal; readable/writable

Types of Counters and Timers

Free-Running Counter

- this counter runs continuously and it is only readable; may set flags or generate an interrupt signal when it reach its maximum count

Timer Applications

Time Delay

 timer register can be loaded with a certain value to produce a delay; in the case of free-running counter the program needs to record the timer reading at a starting point, add the delay count to that reading and keep comparing the readings until a match is found

Timer Applications

Pulse Wave Generation

 to produce a periodic wave (square wave @ 50% duty cycle for example), the time delay for ON-time and OFF-time is the same

Pulse Width Measurement

 to measure a pulse-width, the program begins the counter on the rising edge and stops at the falling edge

Timer Applications

Timer in the Counter Mode

- the timer register can be set up as a **counter** to count pulses representing events
- the timer is not incremented by an internal clock but by an **external pulses** which may include:
 - external clocks
 - sensors (mechanical, optical, etc.)
 - signals from other hardware modules

Timers in PIC16F877A

Timer0 Module

- an 8-bit readable and writable timer/counter
- 8-bit software programmable prescaler
- Interrupt on overflow from FFh to 00h
- Internal or external clock select
- Edge select for external clock

Timer1 Module

- a 16-bit timer/counter consisting of two 8-bit registers (TMR1H and TMR1L) which are readable and writable.
- TMR1 interrupt is generated on overflow, if enabled
- Has two modes: Timer or Counter

Timers in PIC16F877A

Timer2 Module

- is an 8-bit timer with a prescaler and a postscaler. It can be used as the PWM time base for the PWM mode of the CCP module(s)
- TMR2 register is readable and writable and is cleared on any device Reset
- has an 8-bit period register, PR2
- Timer2 increments from 00h until it matches PR2 and then resets to 00h on the next increment cycle
- the match output of TMR2 goes through a 4-bit postscaler (which gives a 1:1 to 1:16 scaling inclusive) to generate a TMR2 interrupt

Timers in PIC16F877A

- Capture, Compare & PWM Module
 - Each Capture/Compare/PWM (CCP) module contains a 16-bit register which can operate as a:
 - 16-bit Capture register
 - 16-bit Compare register
 - PWM Master/Slave Duty Cycle register

In this unit...

- This unit deals with the following timers:
 - Timer1 (Timer Mode)
 - Timer2
 - CCP Module

Timer1

- In **Timer mode**, Timer1 increments every instruction cycle. In **Counter mode**, it increments on every rising edge of the external clock input.
- Timer1 can be enabled/disabled by setting or clearing control bit, TMR10N (T1CON<0>).
- Timer1 can be enabled/disabled by setting/clearing TMR1 interrupt enable bit, TMR1IE (PIE1<0>).
- Timer1 register is TMR1 (TMR1H:TMR1L).

Timer1 Control Register (T1CON)

REGISTER 6-1: T1CON: TIMER1 CONTROL REGISTER (ADDRESS 10h)

U-0	U-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

10h	T1CON	_	_	T1CKPS1	T1CKPS0	T10SCEN	T1SYNC	TMR1CS	TMR10N	00	0000	uu	uuuu

Legend: x = unknown, u = unchanged, - = unimplemented, read as '0'. Shaded cells are not used by the Timer1 module.

Note 1: Bits PSPIE and PSPIF are reserved on the 28-pin devices; always maintain these bits clear.

Timer1 (Timer Mode)

- Timer mode is selected by clearing the TMR1CS (T1CON<1>) bit.
- In this mode, the input clock to the timer is FOSC/4.
- The timeout can be calculated given the oscillator frequency (Fosc) of the MCU and a prescaler value.

$$timeout = \frac{1}{\frac{F_{OSC}}{4}} \times prescaler \times TimerMaxCount$$
 (1)

For example, given Fosc = 4MHz and a prescaler of 1:4

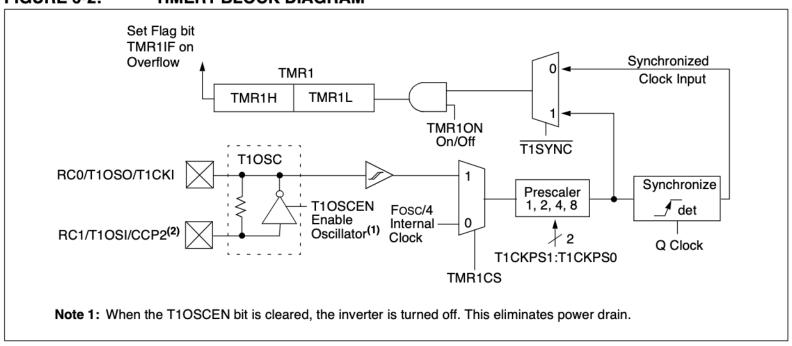

timeout =
$$\frac{1}{\frac{4\text{MHz}}{4}} \times 4 \times 65536 = \frac{1}{1\times10^6} \times 262144 = 0.2621s$$

Timer1 Module

FIGURE 6-2: TIMER1 BLOCK DIAGRAM

Timer1 Module Block Diagram

Example (Timer1)

• Configure Timer1 to generate an interrupt every 0.5 seconds. Create an ISR for Timer1 overflow interrupt where it blinks the LED connected at RA0. Assume Fosc = 4MHz and the timer operates in Timer Mode.

Using a prescaler of 1:8 and since the timeout is given at 0.5s

From Equation 1:
$$0.5s = \frac{1}{\frac{4MHz}{4}} \times 8 \times TimerMaxCount$$

Timer Max Count must be determined in order to have a timeout of 0.5s

$$TimerMaxCount = 62500$$

The value of Timer Max Count will be used to reload the timer after interrupt.

```
void main(void)
 ADCON1 = 0x6;
                    // set all pins in PORTA as digital I/O
  TRISA = 0x00;
                    // sets all of PORTA to output
  RA0 = 0;
                    // initialize RAO to 0 (LED off)
                    // 1:8 prescaler, internal clock, Timer1 off
  T1CON = 0x30;
                    // enable Timer1 overflow interrupt (PIE1 reg)
  TMR1IE = 1;
  TMR1IF = 0;
                     // reset interrupt flag (PIR1 reg)
  PEIE = 1;
                    // enable all peripheral interrupt (INTCON reg)
                    // enable all unmasked interrupts (INTCON reg)
  GIE = 1;
                    // counter starts counting at 0x0BDC (3036)
  TMR1 = 0x0BDC;
                    // Turns on Timer1 (T1CON reg)
  TMR1ON = 1;
 for(;;)
                     // foreground routine
```

The value of 0x0BDC (3036) was derived from 65536-62500. By starting the counter at this value, the 0.5s timeout can be achieved.

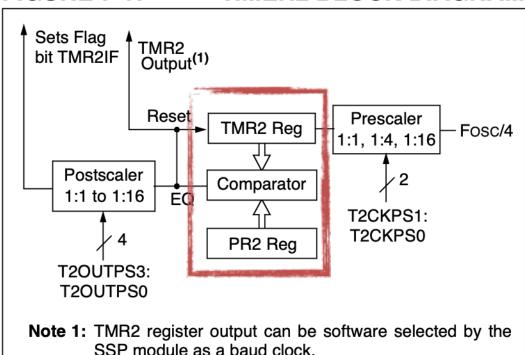

Timer2

- Unlike Timer0 and Timer1, this timer module does not generate interrupt upon overflow.
- It generates an interrupt when its value will be equal to the period register (PR2) and resets to 00h.
- PR2 can be read or written to and is also an 8-bit register.
- Timer2 register is **TMR2**.

92h	PR2	Timer2 Period Register								1111	1111	1111	1111

Legend: x = unknown, u = unchanged, - = unimplemented, read as '0'. Shaded cells are not used by the Timer2 module.

Note 1: Bits PSPIE and PSPIF are reserved on 28-pin devices; always maintain these bits clear.

Timer2 Timeout

- Timer2 increments every clock cycle (Fosc/4).
- The timeout can be calculated given the oscillator frequency (Fosc) of the MCU and a prescaler value similar to Timer0.

$$timeout = \frac{1}{\frac{F_{OSC}}{4}} \times prescaler \times TimerMaxCount$$
 (1)

For example, given Fosc = 4MHz and a prescaler of 1:4

timeout =
$$\frac{1}{\frac{4\text{Mhz}}{4}} \times 4 \times 256 = \frac{1}{1 \times 10^6} \times 1024 = 1.024 \text{ms}$$

Example (Timer2)

 Generate a pulse-wave with a frequency of 1000Hz at 50% duty cycle. The output pulsewave will be at RAO. Assume Fosc = 4MHz.

Determining the period given the frequency of 1000Hz:

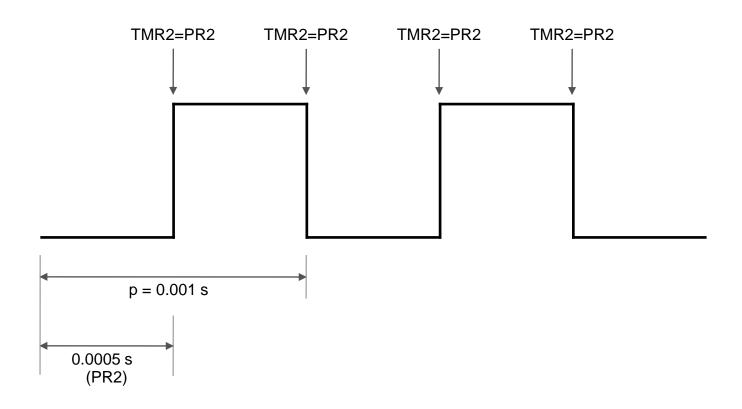

$$p = \frac{1}{f} = \frac{1}{1000} = 0.001$$
s

Using a prescaler of 1:4 for Timer2, we can calculate the Timer Max Count at half-cycle:

From Equation 1:
$$0.0005s = \frac{1}{\frac{4Mhz}{4}} \times 4 \times TimerMaxCount$$

TimerMaxCount = 125

Therefore, the value of PR2 must be set to 125 to match it to TMR2. When TMR2=PR2, the timeout for the half cycle is achieved then an interrupt can be generated.

Every time TMR2 would be equal to PR2, interrupt is generated and the output of RA0 is toggled.

```
void main(void)
  ADCON1 = 0x6; // set all pins in PORTA as digital I/O
  TRISA = 0 \times 00;
                  // sets all of PORTA to output
  RA0 = 0;
                 // initialize RAO to 0
  T2CON = 0x01;
                 // 1:4 prescaler, Timer2 off
  TMR2IE = 1;
                 // enable Timer2/PR2 match interrupt (PIE1 reg)
  TMR2IF = 0;
                  // reset interrupt flag (PIR1 reg)
                  // enable all peripheral interrupt (INTCON reg)
  PEIE = 1;
  GIE = 1;
                  // enable all unmasked interrupts (INTCON reg)
  PR2 = 0x7D; // match value for TMR2(125)at half cycle
                  // Turns on Timer2 (T2CON reg)
  TMR2ON = 1;
  for(;;)
                  // foreground routine
```

The value of 0x7D (125) was derived from Timer Max Count at half-cycle timeout for the frequency of 1000Hz.

CCP Module

- There are 2 CCP modules: CCP1 and CCP2
- Both the CCP1 and CCP2 modules are identical in operation, with the exception being the operation of the special event trigger.

TABLE 8-1: CCP MODE – TIMER RESOURCES REQUIRED

CCP Mode	Timer Resource
Capture	Timer1
Compare	Timer1
PWM	Timer2

TABLE 8-2: INTERACTION OF TWO CCP MODULES

CCPx Mode	CCPy Mode	Interaction			
Capture	Capture	Same TMR1 time base			
Capture	Compare	The compare should be configured for the special event trigger which clears TMR1			
Compare	Compare	The compare(s) should be configured for the special event trigger which clears TMR1			
PWM	PWM	The PWMs will have the same frequency and update rate (TMR2 interrupt)			
PWM	Capture	None			
PWM	Compare	None			

CCP1 Module

- Capture/Compare/PWM Register 1 (CCPR1) is comprised of two 8-bit registers: CCPR1L (low byte) and CCPR1H (high byte).
- The CCP1CON register controls the operation of CCP1.
- The special event trigger is generated by a compare match and will reset Timer1.

CCP2 Module

- Capture/Compare/PWM Register 2 (CCPR2) is comprised of two 8-bit registers: CCPR2L (low byte) and CCPR2H (high byte).
- The CCP2CON register controls the operation of CCP2.
- The special event trigger is generated by a <u>compare</u> match and <u>will reset Timer1</u> and <u>start an A/D</u> conversion (if the A/D module is enabled).

0 = None of the RB7:RB4 pins have changed state

Capture Mode

- In Capture mode, CCPR1H:CCPR1L captures the 16-bit value of the TMR1 register when an event occurs on pin RC2/CCP1.
- An event is defined as one of the following:
 - Every falling edge
 - Every rising edge
 - Every 4th rising edge
 - Every 16th rising edge
- The type of event is configured by control bits, CCP1M3:CCP1M0 (CCPxCON<3:0>).

| 11xx = PWM mode
```

Interrupt enable is at PIE1 register while the flag at PIR1 register for CCP1 while interrupt enable and flag for CCP2 are at PIE2 and PIR2 respectively. See

PIC16F87X data sheet for more details.

Example (Capture)

 Determine the period (ms) of a pulse-wave signal input at RC2. Assume Fosc = 4Mhz.

Using a prescaler of 1:8 for **Timer1**, we can calculate the <u>time per increment</u>:

From Equation 1*:
$$timeout = \frac{1}{\frac{4MHz}{4}} \times 8 \times 1$$
$$timeout = 8 \times 10^{-6} \text{s}$$

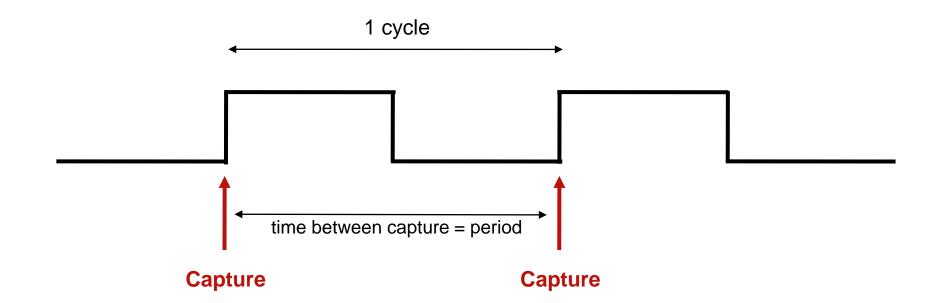

Normalizing the timeout to make it a whole number:

$$timeout_n = 8x10^{-6}s (1x10^6) = 8s$$

The normalization is used to eliminate working with real (floating point) numbers.

^{*} Timer Max Count is set to 1 since we need to determine the timeout per Timer1 increment.

```
void main(void)
  TRISC = 0x04; // set RC2 to input
  T1CON = 0x30; // 1:8 prescaler, Timer1 off
  CCP1CON = 0 \times 05; // capture mode: every rising edge
  CCP1IE = 1; // enable TMR1/CCP1 match interrupt (PIE1 reg)
  CCP1IF = 0;  // reset interrupt flag (PIR1 reg)
  PEIE = 1; // enable all peripheral interrupt (INTCON reg)
  GIE = 1; // enable all unmasked interrupts (INTCON reg)
  TMR1ON = 1;  // Turns on Timer1 (T1CON reg)
  for(;;)
                 // foreground routine
```

CCP1CON must be set to capture mode which generates an interrupt when a rising edge event at RC2 occurs.

The value of the variable *period* is an integer which is in ms. For example, if the value is 500 then it is equivalent to 500 ms.

Frequency above 1000Hz will result in a value of 0.

Compare Mode

- In Compare mode, the 16-bit CCPR1 register value is constantly compared against the TMR1 register pair value.
- When a match occurs, the RC2/CCP1 pin is:
 - Driven high
 - Driven low
 - Remains unchanged
- The action on the pin is based on the value of control bits, CCP1M3:CCP1M0 (CCP1CON<3:0>). At the same time, interrupt flag bit CCP1IF is set.

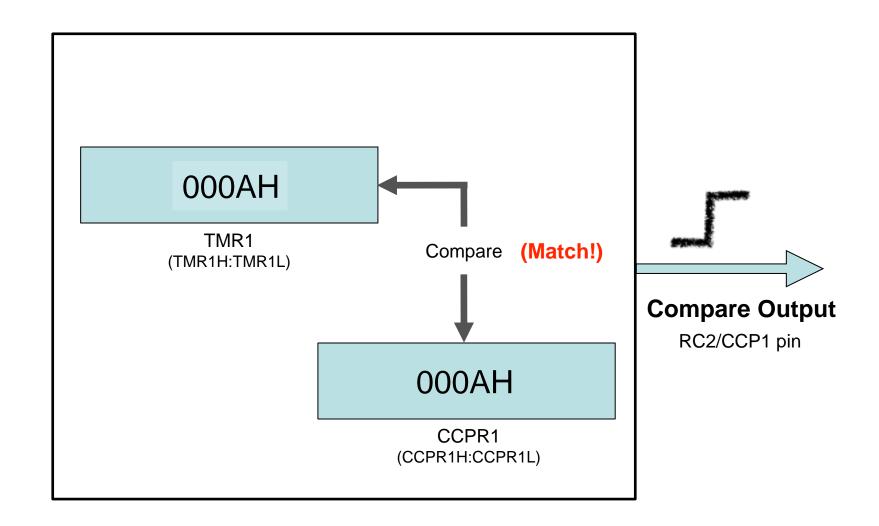

CCP1/CCP2 Control Register (Compare)

	1011 = Compare mode, trigger special event (CCPxIF bit is set, CCPx pin is unaffected); CCP1 resets TMR1; CCP2 resets TMR1 and starts an A/D conversion (if A/D module is enabled)											
		Dieu)										

Interrupt enable is at PIE1 register while the flag at PIR1 register for CCP1 while interrupt enable and flag for CCP2 are at PIE2 and PIR2 respectively. See

11xx = PWM mode

PIC16F87X data sheet for more details.

Example (Compare)

 Generate a pulse-wave with a frequency of 100Hz at 50% duty cycle. The output pulse-wave will be at RA0. Assume Fosc = 4MHz.

Determining the period given the frequency of 1000Hz:

$$p = \frac{1}{f} = \frac{1}{100} = 0.01$$
s

Using a prescaler of 1:4 for Timer1, we can calculate the Timer Max Count at half-cycle:

From Equation 1:
$$0.005s = \frac{1}{\frac{4MHz}{4}} \times 4 \times TimerMaxCount$$

TimerMaxCount = 1250 or 0x4E2

Therefore, CCPR1 must be set to 0x4E2. When TMR1=CCPR1, then it generates an interrupt and toggles the output at RA0.

```
void main(void)
 ADCON1 = 0x6; // set all pins in PORTA as digital I/O
 TRISA = 0x00; // sets all of PORTA to output
                // initialize RAO to 0
 RA0 = 0;
 T1CON = 0x20; // 1:4 prescaler, Timer1 off
 CCP1CON = 0x0A; // compare mode: generate interrupt on match
 CCP1IE = 1;
                // enable TMR1/CCP1 match interrupt (PIE1 reg)
 CCP1IF = 0;
                // reset interrupt flag (PIR1 reg)
 CCPR1 = 0x4E2; // set the match value to TMR1
 GIE = 1;
              // enable all unmasked interrupts (INTCON reg)
 TMR1ON = 1;
                // Turns on Timer1 (T1CON reg)
 for(;;)
                // foreground routine
```

CCP1CON must be set to **compare mode** which generates an interrupt when **TMR1=CCPR1**. This example does not use the CCP1 output at RC2.

Note 1: The PSP is not implemented on 28-pin devices; always maintain these bits clear.

For CCP1 module

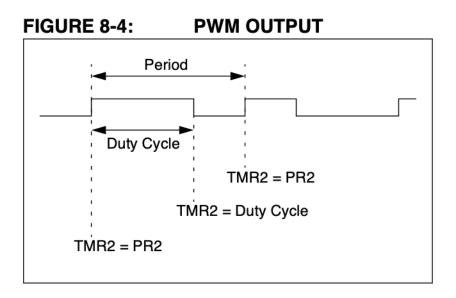

For CCP2 module

Common to both, including TMR1

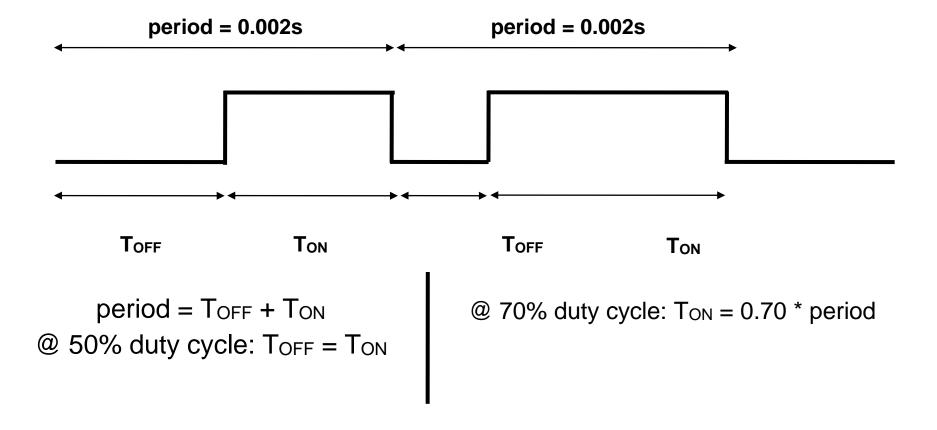

PWM

• In Pulse Width Modulation (PWM) mode, the CCPx pin produces <u>up to a 10-bit resolution PWM output</u>. Since the CCP1 pin is multiplexed with the PORTC data latch, the TRISC<2> bit must be cleared to make the CCP1 pin an output.

PWM Period

 The PWM period is specified by writing to the PR2 register. The PWM period can be calculated using the following formula:

PWM Period =
$$[(PR2) + 1] \cdot 4 \cdot Tosc \cdot$$
(TMR2 Prescale Value)

- When TMR2 is equal to PR2, the following three events occur on the next increment cycle:
 - TMR2 is cleared
 - The **CCP1** pin is set (exception: if PWM duty cycle = 0%, the CCP1 pin will not be set)
 - The **PWM duty cycle** is latched from **CCPR1L** into **CCPR1H**

Note: Tosc = 1/Fosc where is Fosc is oscillator frequency.

bit 7-6 Unimplemented: Read as '0' CCPxX:CCPxY: PWM Least Significant bits bit 5-4 Capture mode: Unused. Compare mode: Unused. PWM mode: I These bits are the two LSbs of the PWM duty cycle. The eight MSbs are found in CCPRxL. CCPxM3:CCPxM0: CCPx Mode Select bits bit 3-0 0000 = Capture/Compare/PWM disabled (resets CCPx module) 0100 = Capture mode, every falling edge 0101 = Capture mode, every rising edge 0110 = Capture mode, every 4th rising edge 0111 = Capture mode, every 16th rising edge 1000 = Compare mode, set output on match (CCPxIF bit is set) 1001 = Compare mode, clear output on match (CCPxIF bit is set) 1010 = Compare mode, generate software interrupt on match (CCPxIF bit is set, CCPx pin is unaffected) 1011 = Compare mode, trigger special event (CCPxIF bit is set, CCPx pin is unaffected); CCP1 resets TMR1; CCP2 resets TMR1 and starts an A/D conversion (if A/D module is enabled) _ 11xx = PWM mode

Interrupt enable is at PIE1 register while the flag at PIR1 register for CCP1 while interrupt enable and flag for CCP2 are at PIE2 and PIR2 respectively. See

PIC16F87X data sheet for more details.

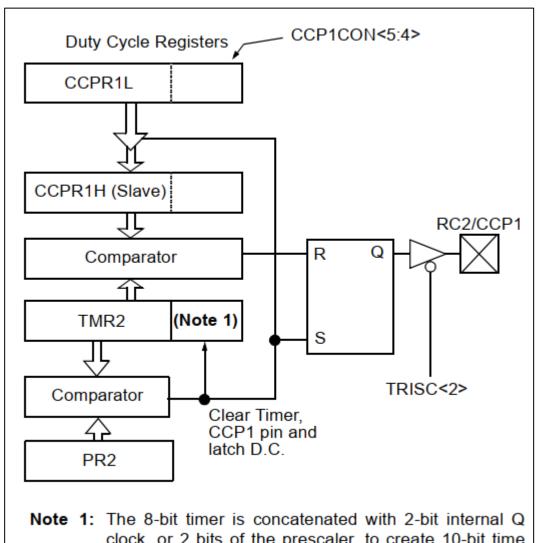

PWM Duty Cycle

- The **PWM duty cycle** is specified by writing to the **CCPR1L register** and to the **CCP1CON<5:4> bits**.
- Up to 10-bit resolution is available.
- The <u>CCPR1L</u> contains the eight MSBs and the <u>CCP1CON<5:4></u> contains the two LSBs.
- This 10-bit value is represented by **CCPR1L:CCP1CON<5:4>**. The following equation is used to calculate the **PWM duty cycle in time**:

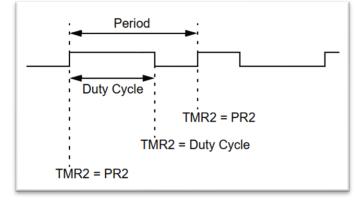

- CCPR1L and CCP1CON<5:4> can be written to at any time, but the <u>duty</u> cycle value is not latched into CCPR1H until after a match between PR2 and TMR2 occurs (i.e., the period is complete).
- In PWM mode, CCPR1H is a read-only register.

Simplified PWM Block Diagram

clock, or 2 bits of the prescaler, to create 10-bit time base.

Setup for PWM

- The following steps should be taken when configuring the CCP module for PWM operation:
 - 1. Set the **PWM period** by writing to the **PR2** register.
 - 2. Set the **PWM duty cycle** by writing to the **CCPR1L register and CCP1CON<5:4> bits**.
 - 3. Make the **CCP1 pin** an **output** by clearing the **TRISC<2> bit**.
 - 4. Set the **TMR2 prescale value** and enable **Timer2** by writing to **T2CON**.
 - 5. Configure the CCP1 module for PWM operation.

Example (PWM)

• Configure the CCP1 Module to operate in **PWM mode** which outputs a signal with a 70% duty cycle at a frequency of 500Hz. Assume that Fosc = 4MHz.

Calculating the value of **PR2** given a period of 1/500Hz (0.002s) and **Timer2** prescaler at 1:16:

From Equation 2:
$$0.002s = [(PR2) + 1] \times 4 \times (2.5 \times 10^{-7}) \times 16$$

 $PR2 = 124 (0 \times 7C)$

Calculating the **10-bit resolution value** given a **duty cycle of 70%.** The **PWM duty cycle** should be given in $\underline{\text{time}}$ that is $0.7 \times 0.002s = 1.4\text{ms}$.

From Equation 3:
$$1.4 \times 10^{-3} = (CCPR1L: CCP1CON < 5: 4 >) \times \frac{1}{4 \text{MHz}} \times 16$$

$$(CCPR1L: CCP1CON < 5: 4 >) = 350 \text{ or } 0101 \text{ } 0111 \text{ } 10_2$$

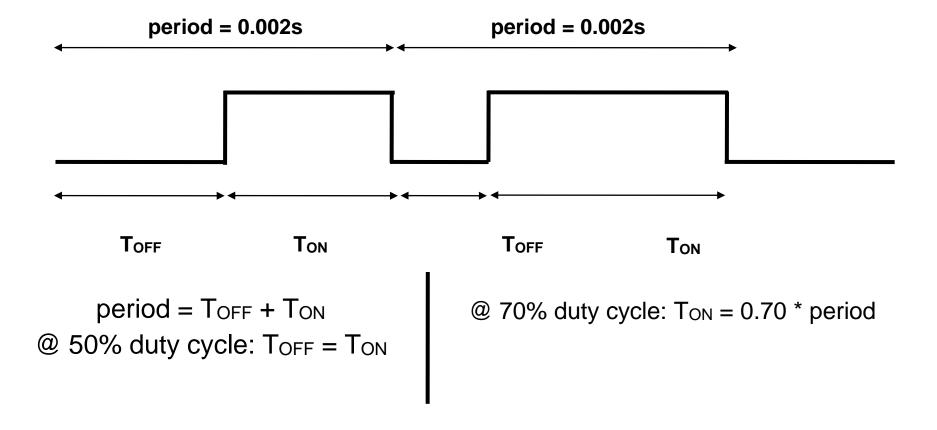

$$CCPR1L = 0101 \text{ } 0111_2 \text{ or } 0 \times 57$$

$$CCP1CON < 5: 4 >= 10_2 \text{ or } 0 \times 2$$

CCP1CON sets the **2-bit LSB of the PWM resolution** as well as **setting the mode to PWM**. See the PIC16F87X data sheet for more information.
